

Persona-axis projections by model (z-scored across models)

How to read

Each cell shows how much a model deviates from the cross-model average on a given persona axis, expressed as a z-score (units of standard deviation).

- Red → model scores higher than peers on that trait.
- Blue → model scores lower than peers.
- Near-white → typical / no separation.

Rows are grouped by model family (left stripe). Reading down a column tells you which families lean which way; reading across a row gives that model's signature.
